Matlab non planer array doa estimation Tutorial

matlab non planer array doa estimation is a critical topic in the field of array signal processing, especially for applications involving three-dimensional source localization such as radar, sonar, wireless communications, and acoustic imaging. Unlike planar arrays, non-planar (or volumetric) arrays provide the advantage of estimating the direction of arrival (DOA) of signals in both azimuth and elevation angles, offering a more comprehensive spatial understanding of incoming signals. MATLAB, being a versatile platform for algorithm development and simulation, provides extensive tools and functions to implement and analyze non-planar array DOA estimation techniques. This article explores the fundamental concepts, practical implementation, and advanced approaches to DOA estimation using non-planar arrays in MATLAB.

Understanding Non-Planar Arrays and DOA Estimation

What Are Non-Planar Arrays?

Non-planar arrays are sensor configurations where antennas or microphones are arranged in three-dimensional space, not confined to a single plane. These arrays are designed to capture spatial information in both the azimuth and elevation domains, making them suitable for 3D source localization. Common non-planar array geometries include:

- Spherical arrays
- Conical arrays
- Volumetric arrays (e.g., tetrahedral, cubic)
- Random 3D configurations

The key advantage of non-planar arrays is their ability to resolve the elevation angle, which planar arrays often struggle with due to their limited spatial diversity.

What Is DOA Estimation?

Direction of Arrival (DOA) estimation involves determining the angles at which signals arrive at an array of sensors. Accurate DOA estimation enables localization of the signal source in space. The main parameters typically estimated are:

- Azimuth angle (horizontal direction)
- Elevation angle (vertical direction)

Effective DOA estimation relies on analyzing the received signals, their phase differences, and amplitude variations across array elements.

Mathematical Foundations of Non-Planar Array DOA Estimation

Signal Model for Non-Planar Arrays

The received signal at the array can be modeled as:

$$ \mathbf{x}(t) = \mathbf{a}(\theta, \phi) s(t) + \mathbf{n}(t) $$

where:

- $\mathbf{x}(t)$ is the vector of signals received at each sensor.
- $\mathbf{a}(\theta, \phi)$ is the steering vector, dependent on azimuth θ and elevation ϕ.
- $s(t)$ is the source signal.
- $\mathbf{n}(t)$ is additive noise.

The steering vector \ encapsulates the phase shifts across sensors due to the wavefront's incident angles and the array geometry.

Steering Vector for 3D Arrays

For a non-planar array, the steering vector is defined as:

$$ \mathbf{a}(\theta, \phi) = \left[e^{-j \mathbf{k} \cdot \mathbf{r}_1}, e^{-j \mathbf{k} \cdot \mathbf{r}_2}, \dots, e^{-j \mathbf{k} \cdot \mathbf{r}_N} \right]^T $$

where:

- $\mathbf{k}$ is the wave vector, related to the incident angles.
- $\mathbf{r}_n$ is the position vector of the n^{th} sensor.
- N is the total number of sensors.

The wave vector components are:

$$\mathbf{k} = \frac{2\pi}{\lambda} [\sin \phi \cos \theta, \sin \phi \sin \theta, \cos \phi]$$

Implementing Non-Planar Array DOA Estimation in MATLAB

Step 1: Define the Array Geometry

The first step involves specifying the 3D positions of the array elements. For example, a tetrahedral array can be defined as:

```matlab

% Define positions of sensors in 3D space (in meters)

sensor_positions = [

0, 0, 0; % Sensor 1 at origin

1, 0, 0; % Sensor 2 along x-axis

0.5, sqrt(3)/2, 0; % Sensor 3 in xy-plane

0.5, sqrt(3)/6, sqrt(6)/3 % Sensor 4 in 3D space

];

```

This configuration provides volumetric diversity essential for 3D DOA estimation.

Step 2: Simulate Signal Reception

Generate a simulated signal arriving at specified angles:

```matlab

% Define source parameters

theta_true = 45; % Azimuth in degrees

phi_true = 30; % Elevation in degrees
```

```
frequency = 1000; % Signal frequency in Hz

c = 340; % Speed of sound or speed of wave in m/s

lambda = c / frequency;

% Convert angles to radians

theta_rad = deg2rad(theta_true);

phi_rad = deg2rad(phi_true);

% Generate wave vector

k = (2 pi / lambda) [sin(phi_rad)cos(theta_rad), sin(phi_rad)sin(theta_rad), cos(phi_rad)];

% Generate received signals at each sensor

num_snapshots = 200; % Number of snapshots

s = exp(1j2pirand(1, num_snapshots)); % Random source signal

% Calculate steering vectors for each sensor

A = zeros(length(sensor_positions), num_snapshots);

for n = 1:length(sensor_positions)

r = sensor_positions(n, :);

phase_shift = exp(-1j (k r'));

A(n, :) = phase_shift.' s;

end
```

Step 3: Apply DOA Estimation Algorithms

In MATLAB, several algorithms are available for DOA estimation, such as MUSIC, ESPRIT, and

Capon. For non-planar arrays, the MUSIC algorithm is popular.

```matlab
% Compute the sample covariance matrix
R = (A A') / size(A, 2);
% Define grid of angles
azimuths = 0:1:360;
elevations = 0:1:90;
% Initialize spectrum
music_spectrum = zeros(length(elevations), length(azimuths));
% Perform MUSIC spectrum search
for i = 1:length(elevations)
for j = 1:length(azimuths)
% Convert angles to radians
theta = deg2rad(azimuths(j));
phi = deg2rad(elevations(i));
% Compute steering vector
k_test = (2pi / lambda) [sin(phi)cos(theta), sin(phi)sin(theta), cos(phi)];
a_test = zeros(length(sensor_positions),1);
for n = 1:length(sensor_positions)
r = sensor_positions(n, :);
a_test(n) = exp(-1j (k_test r'));
```

```
end

% Calculate MUSIC spectrum

music_spectrum(i,j) = 1 / (a_test' (R \ a_test));

end

end

% Plot MUSIC spectrum

figure;

imagesc(azimuths, elevations, 20log10(abs(music_spectrum)));

xlabel('Azimuth (degrees)');

ylabel('Elevation (degrees)');

title('3D MUSIC Spectrum for Non-Planar Array');

colorbar;
```

The peaks in the spectrum indicate the estimated DOA angles.

Advanced Techniques for Non-Planar Array DOA Estimation

Multiple Signal Classification (MUSIC)

MUSIC exploits the eigenstructure of the covariance matrix, separating signal and noise subspaces to estimate the DOA. It provides high resolution but requires accurate array calibration.

Estimating DOA with ESPRIT

ESPRIT (Estimation of Signal Parameters via Rotational Invariance Techniques) can be extended to 3D arrays with proper array design, offering computational efficiency.

Sparse Array Techniques

Compressed sensing and sparse signal reconstruction methods can improve DOA estimates when the number of sensors is limited or signals are sparse in the angular domain.

Using MATLAB Toolboxes

MATLAB?s Phased Array System Toolbox offers functions like `phased.MUSICEstimator`, `phased.ESPRITEstimator`, and `phased.SphericalArray` that facilitate implementation of non-planar array DOA estimation.

Challenges and Best Practices

- **Array Calibration:** Precise knowledge of sensor positions is critical for accurate DOA estimation.
- **Mutual Coupling:** Electromagnetic interactions between sensors can distort measurements; calibration or compensation is necessary.
- **Noise and Interference:** Robust algorithms and signal preprocessing improve estimation under adverse conditions.
- **Computational Complexity:** High-resolution methods like MUSIC are computationally intensive; efficient algorithms or hardware acceleration can help.

Matlab Non-Planar Array DOA Estimation: A Comprehensive Guide

Introduction

In the realm of signal processing and wireless communications, Direction of Arrival (DOA) estimation is a fundamental task that involves determining the direction from which a received signal has originated. Accurate DOA estimation is crucial for applications such as radar, sonar, wireless localization, beamforming, and smart antenna systems. While traditional planar arrays have been extensively studied, non-planar or three-dimensional (3D) array configurations have gained significant attention owing to their ability to resolve signals in three-dimensional space more effectively.

Matlab, as a leading computational environment, offers a rich set of tools and functionalities to implement, simulate, and analyze DOA estimation algorithms, especially for complex array geometries like non-planar arrays. This guide provides an in-depth exploration of DOA estimation techniques tailored to non-planar arrays, emphasizing their implementation in Matlab.

Understanding Non-Planar Arrays

What Are Non-Planar Arrays?

Non-planar arrays are antenna configurations that extend beyond a flat, two-dimensional surface, incorporating elements arranged in three-dimensional space. Unlike uniform linear arrays (ULAs) or uniform rectangular arrays (URAs), non-planar arrays can be configured in various geometries such as:

- Random 3D arrays
- Conical arrays
- Spherical arrays
- Cylindrical arrays
- Conformal arrays

These configurations enable the resolution of azimuth and elevation angles simultaneously, providing full 3D DOA estimation capabilities.

Advantages of Non-Planar Arrays

- Enhanced 3D Spatial Resolution: Ability to distinguish signals arriving from different elevation and azimuth angles.
- Improved Ambiguity Resolution: Reduced array ambiguity, especially in complex environments.
- Flexibility in Deployment: Suitability for applications with spatial constraints or specific orientation requirements.
- Robustness to Signal Multipath: Better discrimination of direct and reflected paths due to spatial diversity.

Fundamentals of DOA Estimation for Non-Planar Arrays

Signal Model

Consider an array with M elements receiving K narrowband signals from different directions in space. The received signal vector at time t can be modeled as:

$$
\mathbf{x}(t) = \mathbf{A}(\boldsymbol{\theta}, \boldsymbol{\phi}) \mathbf{s}(t) + \mathbf{n}(t)
$$

\]

Where:

- \(\mathbf{x}(t) \): \(M \times 1 \) received signal vector
- \(\mathbf{A}(\boldsymbol{\theta}, \boldsymbol{\phi}) \): \(M \times K \) steering matrix, functions of azimuth \(\boldsymbol{\phi} \) and elevation \(\boldsymbol{\theta} \)
- \(\mathbf{s}(t) \): Source signals
- \(\mathbf{n}(t) \): Noise vector

Steering Vector for Non-Planar Arrays

Unlike planar arrays, the steering vector \(\mathbf{a}(\theta, \phi) \) depends heavily on the 3D positions of the array elements:

\[

a_m(\theta, \phi) = e^{j \frac{2\pi}{\lambda} \mathbf{r}_m \cdot \mathbf{\hat{k}}(\theta, \phi)}

\]

Where:

- \(\mathbf{r}_m \): 3D coordinate of the \(m^{th} \) element
- \(\lambda \): Wavelength of the signals
- \(\mathbf{\hat{k}}(\theta, \phi) \): Wave vector pointing in the direction \((\theta, \phi) \)

This expression captures the phase shifts across the array elements due to their spatial arrangement.

Implementing Non-Planar DOA Estimation in Matlab

Step 1: Array Geometry Definition

The first step involves defining the 3D positions of the array elements. Consider a non-planar array such as a conical array:

```matlab
```

```
% Number of elements

M = 12;

% Define parameters

radius = 1; % meters

height = 0.5; % meters

% Generate array element positions in 3D

theta_array = linspace(0, 2pi, M);

r = radius ones(1, M);

z = height rand(1, M); % random z-coordinate for non-planarity

% Cartesian coordinates

x = r . cos(theta_array);

y = r . sin(theta_array);

positions = [x; y; z]; % 3 x M matrix
```

This configuration can be modified to match specific geometries like spherical or cylindrical arrays.

Step 2: Signal Simulation

Simulate incoming signals with known DOAs to evaluate algorithm performance:

```matlab
% Define true DOAs

true_theta = 30; % degrees elevation

true_phi = 45; % degrees azimuth
```

% Convert to radians

theta_rad = deg2rad(true_theta);

phi_rad = deg2rad(true_phi);

% Wavelength

lambda = 0.3; % meters (e.g., 1 GHz frequency)

% Generate steering vector

k = 2pi / lambda;

k_vec = k [cos(theta_rad)cos(phi_rad); cos(theta_rad)sin(phi_rad); sin(theta_rad)];

% Compute phase shifts for each element

phase_shifts = positions' k_vec; % M x 1 vector

steering_vector = exp(1j phase_shifts);

% Generate source signal

num_snapshots = 200;

signal = exp(1j 2 pi rand(1, num_snapshots));

% Received data

X = repmat(steering_vector, 1, num_snapshots) signal + noise(M, num_snapshots);

```

Where `noise()` represents additive white Gaussian noise.

Step 3: Covariance Matrix Estimation

Estimate the covariance matrix from the received data:

```matlab

Rxx = (X X') / num_snapshots;

```

Step 4: Applying DOA Estimation Algorithms

Common algorithms suitable for non-planar arrays include:

- Multiple Signal Classification (MUSIC)
- Estimation of Signal Parameters via Rotational Invariance Techniques (ESPRIT)
- Sparse Bayesian Methods

MUSIC Algorithm Implementation:

- Eigen-decompose the covariance matrix:

```matlab

[E, D] = eig(Rxx);

% Sort eigenvalues

[eigenvalues, idx] = sort(diag(D), 'descend');

E = E(:, idx);

```

- Determine noise subspace:

```matlab

noise_eigenvectors = E(:, K+1:end);

```

- Search over a grid of possible DOAs:
```

```matlab
theta_scan = linspace(0, pi/2, 90); % elevation
phi_scan = linspace(0, 2pi, 180); % azimuth
P_MUSIC = zeros(length(theta_scan), length(phi_scan));
for i = 1:length(theta_scan)
for j = 1:length(phi_scan)
% Compute steering vector
kx = k cos(theta_scan(i)) cos(phi_scan(j));
ky = k cos(theta_scan(i)) sin(phi_scan(j));
kz = k sin(theta_scan(i));
steering_vec = exp(1j (positions' [kx; ky; kz]));
% MUSIC pseudo-spectrum
P_MUSIC(i,j) = 1 / (steering_vec' (noise_eigenvectors noise_eigenvectors') steering_vec);
end
end
```

- Identify peaks in the pseudo-spectrum to estimate DOAs:

```matlab
[max_val, max_idx] = max(P_MUSIC(:));
[peak_i, peak_j] = ind2sub(size(P_MUSIC), max_idx);
```

```
estimated_theta = rad2deg(theta_scan(peak_i));

estimated_phi = rad2deg(phi_scan(peak_j));
```
